

ABSTRACT OF THE DISCLOSURE

A freestanding candle has a flame-resistant sheet adhered to a wick support and to a fuel body in a location proximate to the lower end of a wick. The sheet reduces the risk of fire hazards that arise during the later stages of candle burning, which are characterized by a thin candle floor and a pool of liquid fuel surrounding the wick support. The wick support is made longer and sealingly adhered to the sheet to further reduce the risk of fire hazards. The structural combination of the wick support, the sealant, and the sheet facilitates even burning during the life of the candle and self-extinguishment of the flame at the end stage of burning.
